AN OUTBREAK OF GASTROENTERITIS
Clearwater, Washington

A logging camp on the Olympic peninsula was the site of an outbreak of gastroenteritis in August, September, and early October of this year due to heavy contamination of the water supply by sewage effluent. The illness was mild in most cases and was characterized by abrupt onset, watery non-bloody diarrhea, low grade fever, nausea and abdominal cramps. Its duration ranged from 1 to 4 days; repeated attacks were frequent although the first illness tended to be the most severe. New employees became ill with regularity, usually within 48 hours of arrival.

An Outbreak of Gastroenteritis -

ATLANTA 22-64

An average of 130 loggers are employed by the camp. Seventy-five of these men live in the camp bunk house and take their meals in the camp mess hall. The remaining loggers live at home and have little contact with the bunk house residents. They seldom eat in the mess hall, but regularly drink the camp water which is hauled to the work sites in the forest.

AN OUTBREAK OF GASTROENTERITIS

Clearwater, Washington

(Continued from front page)

In a survey of the incidence of gastroenteritis, interviews were held with bunk house residents, loggers who lived at home, family members of loggers who lived at home, and people living in the Clearwater area who had no relation to the logging camp. Eighty-eight percent of the loggers were interviewed and the following data obtained:

	Number Interviewed	Number Ill	Percent Ill
Bunk house employees	68	61	89.7
Employees living at home	48	40	83.3
Family members of employees	120	33	27.5
Unrelated persons	129	18	13.9

An extremely dry summer in the Pacific Northwest, where the total rainfall during June, July and August was 4.29 inches, depleted the stream which is the camp's usual source of water. On several occasions during the summer, water from a nearby river was pumped into the camp water tank, chlorinated and used. The epidemiological investigations revealed that the employees had been complaining of poor tasting water on these occasions. Further, it was found that septic tank effluent from the camp was discharged into this river at three sites, one of which was above the intake pipe through which the supplemental water supply was obtained. The chlorination

process used was also found to be inadequate, as coliform counts of samples of tap water collected in camp yielded values as high as 43 MPN.

Examination of stool specimens from patients who were ill resulted in positive cultures of a specific serotype of enteropathogenic *Escherichia coli* 0126:B16. This organism is documented as a cause of infantile diarrhea¹, but has never been implicated as a pathogen in adults.

The etiology of gastroenteritis associated with ingestion of water heavily contaminated with sewage or "sewage poisoning" is obscure. As certain serotypes of enteropathogenic *E. coli* have produced gastrointestinal illness in adult volunteers², the hypothesis that this outbreak might have been caused by this organism was tested in a rectal swab survey. In all, 233 specimens were collected from loggers, their families, and unrelated persons in the area. Complete laboratory data are not available as yet, but preliminary results do not support this hypothesis, as enteropathogenic *E. coli* serotype 0126:B16 is being recovered from all groups with about the same frequency. No other pathogens have been found, but attempts to isolate virus are in progress.

(Reported by Dr. Ernest A. Ager, Chief, Division of Epidemiology, Washington State Department of Health; Dr. Phillip H. Jones, Medical Epidemiologist, Washington State Department of Health; and two EIS Officers.)

INFLUENZA - CURRENT TRENDS

Since publication of the influenza statement prepared by the Public Health Service Advisory Committee on Immunization Practices in June 1965 (MMWR, Vol. 14, No. 24), there have been no outbreaks of influenza documented in the continental United States, and only two reports have been noted from other parts of the world. A moderate outbreak of type B influenza began in Australia in April 1965, and type A2 disease appeared in early May in portions of the Republic of the Philippines.

In Australia, mild epidemics of influenza type B were reported in the States of Queensland, Victoria, and New South Wales during the Australian winter of 1965. The first case, which was reported in Geelong, Victoria, in April 1965, yielded an isolate of type B influenza virus. The same type was recovered from cases in Queensland, Victoria, and New South Wales. Clinically, the illness was characterized by acute onset, fever ranging from 100° to 104°F, headache, myalgia, and sore throat. Nausea and

vomiting were reportedly common during the first 2 days of illness and general weakness was prominent. An outstanding feature was a severe inflammation of the pharynx giving a red velvety appearance. Unlike the A2 influenza epidemic in 1964, the development of cough was unusual. Influenza B viruses were isolated from respiratory tract specimens taken post-mortem from cases of sudden deaths in older groups, both in Victoria and Queensland. Several fatal pneumonias in older children and younger adults also yielded type B influenza virus. Although mortality figures for the various states were incomplete, the available data do not indicate a marked excess mortality.

The epidemic in the Philippines was initially noted in the Manila area, beginning in mid May, and was brought to light primarily through an increased number of admissions to the San Lazaro Infectious Disease Hospital. Subsequent reports from other parts of the Philippines

(Continued on back page)

INFLUENZA - CURRENT TRENDS

(Continued from page 370)

showed slight increases in the weekly incidence of influenza-like illness. The epidemic continued at moderately low levels through the subsequent weeks and spread gradually to other areas. Type A2 influenza virus was isolated, from typical cases, by the Bureau of Research Laboratories. Symptoms were generally mild with deaths occurring only rarely. By early summer, cases had begun to decrease in number and the epidemic in general was on the wane. The reported number of cases appears to be considerably less than that recorded during the 1957 epidemic of Asian influenza.

The influenza prospectus for the United States during 1965-66 is unchanged from that in the statement in June. The last major epidemic of type A influenza occurred generally throughout the United States in 1962-63 and on the west coast during the following year. Although A2 infections appeared at times in widely scattered areas in 1964-65, they reached epidemic levels, as measured by excess mortality, only in certain parts of the Northeast and in Texas and Oklahoma. In view of the 2- to 3-year periodicity of type A influenza, an increased incidence may be expected in the coming season.

The last major outbreak of type B influenza in the United States was in 1961-62. In view of the 4- to 6-year periodicity of influenza B epidemics, type B influenza may also be anticipated during the coming year. This expectation is strengthened by the substantial number of type B strains isolated during the winter 1964-65 in the U. S. and Europe.

The Public Health Service Advisory Committee on Immunization Practices has outlined the influenza immunization schedule recommended for all persons in the "high risk groups" detailed in the statement issued by the Committee on June 11, 1965 (MMWR, Vol. 14, No. 24).

(Reported by the Respiratory Diseases Unit of the Surveillance Section, Epidemiology Branch, CDC.)

THE MORBIDITY AND MORTALITY WEEKLY REPORT, WITH A CIRCULATION OF 14,000, IS PUBLISHED AT THE COMMUNICABLE DISEASE CENTER, ATLANTA, GEORGIA.
